Prior experience and knowledge  
perception, action  
language

participants

space

time

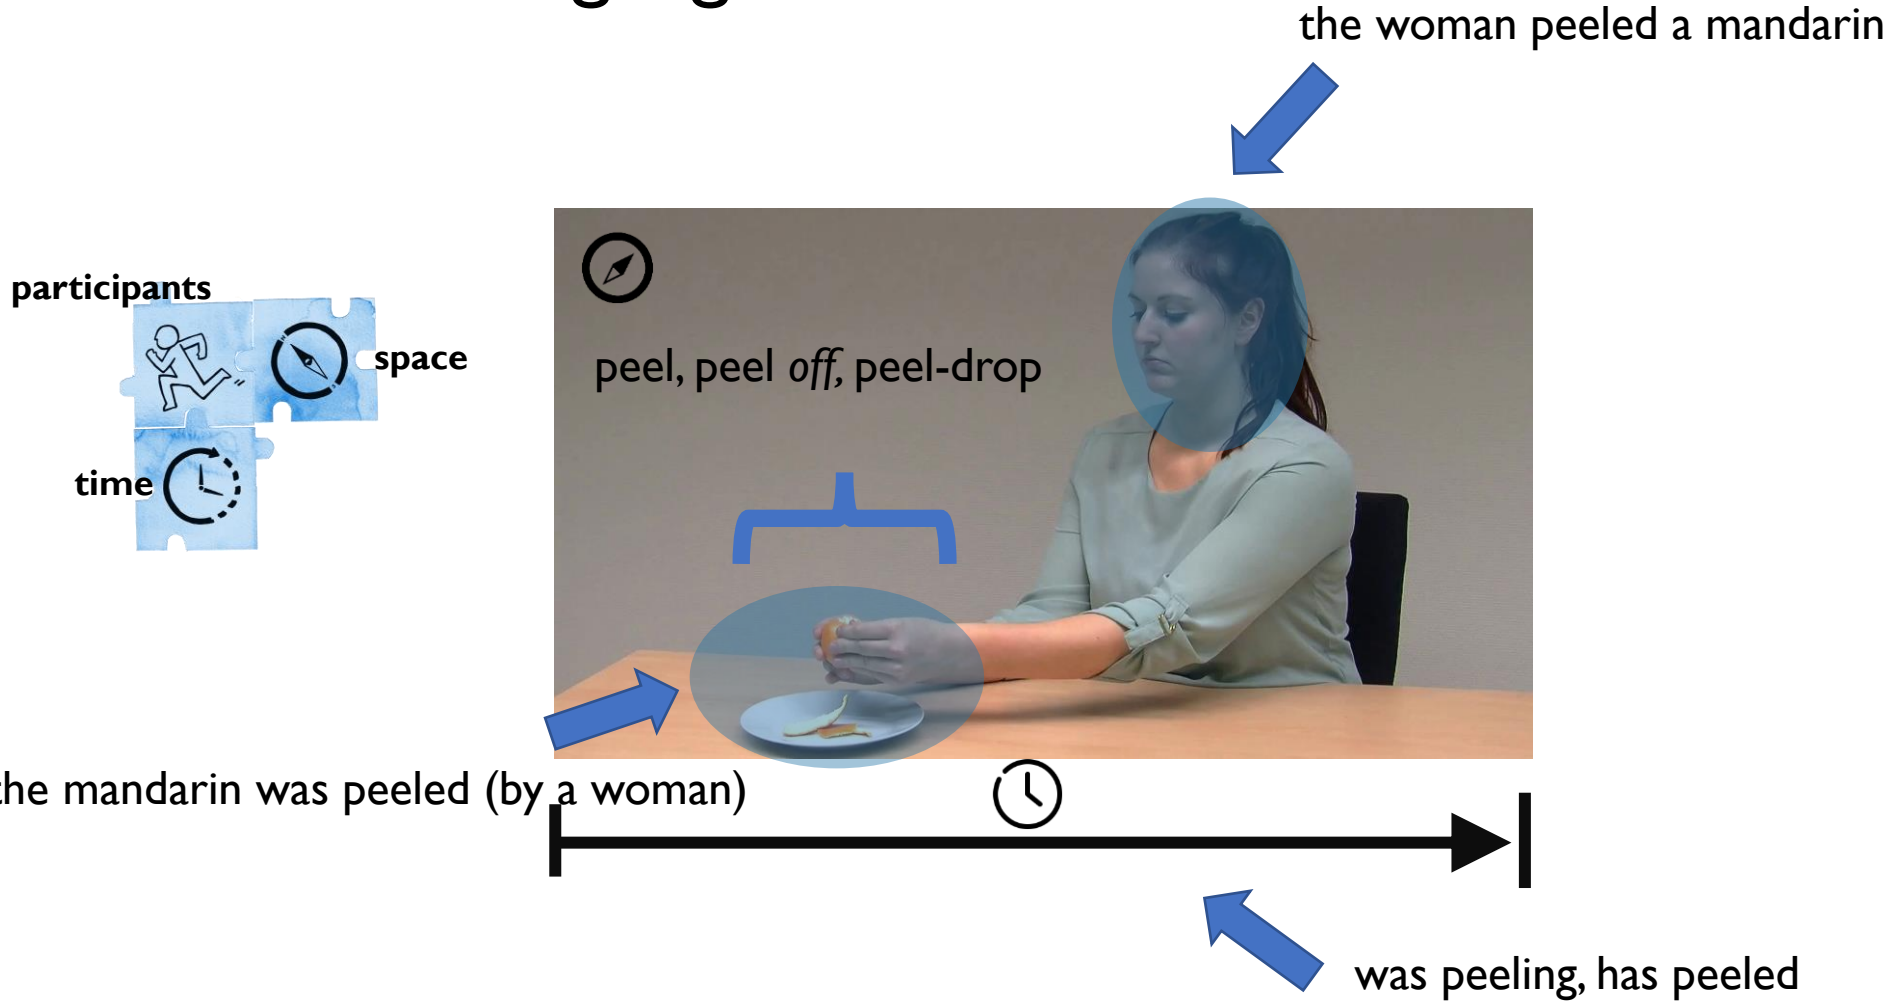

# Events in language

participants

“a woman is peeling a mandarin”

# Events in language: variation

# Questions

participants

To what extent does **variation** in the linguistic expression of event **viewpoints** guide event perception and memory?

Where do we find **general cognitive biases**, unrelated to language use and variation?

# Approaches and methods

1. **Cross-linguistic** analyses of event perception and memory, during linguistic and nonlinguistic tasks
2. **Within-language** analyses of event perception and memory, cued by different types of event descriptions
3. Analyses of **L2 users/bilinguals** of languages that differ along certain dimensions (lexicon, grammar) relevant to event construal

# Linguistic variation: verb semantics

- Talmy (1991; 2000):
  - Languages differ in the **locus** of encoding of event dimensions
  - Languages differ in the semantics typically encoded in the **verbal** lexicon

## MOTION EVENTS: manner of motion vs path of motion

satellite-framing  
verb-framing

A man **walks into** the church  
A man **enters** a church (**on foot**)

## CHANGE OF STATE EVENTS: manner of action vs result of action

satellite-framing  
verb-framing

A woman **pours** juice **into** a glass /  
A woman **pours** the glass **full**  
A woman **fills** a glass (**by pouring**)

# I. Motion events

- a) Motion event description and processing (Eye tracking) in German/French L2
- b) Motion event processing (EEG) in Turkish-Dutch bilinguals

# Language and motion event cognition

- How do speakers of different languages view, linguistically encode and memorize events?
- Measures:
  - Description patterns
  - **Eye movement** patterns during scene encoding
  - **Memory** after scene encoding
  - **Event segmentation**: when do people perceive an event boundary?

# Satellite-/verb-framed languages

## Satellite-framed languages

e.g., English, German, Dutch

*to skate, slide, stroll, run, creep, tiptoe*

*...across/along/to/towards*

High manner saliency

More **attention** to **Manner**

Better **memory** for Manner

## Verb-framed languages

e.g., Greek, Spanish, Turkish

*to enter, cross, 'traverse', 'advance', approach*

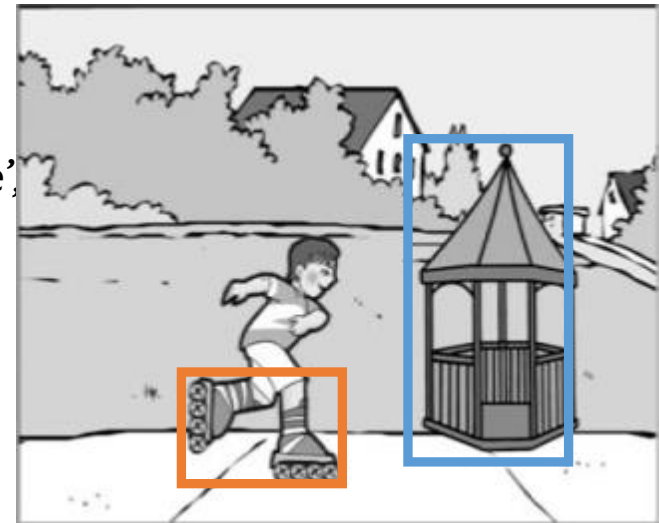

*(...on skates)*

Low manner saliency

More **attention** to **Path**

Better **memory** for Path

Talmy (2000); Slobin (1996)

# Event segmentation: how many events?

“running situation”

Manner-focus

“approaching situation”

“entering situation”

Path-focus

# Stimuli

critical

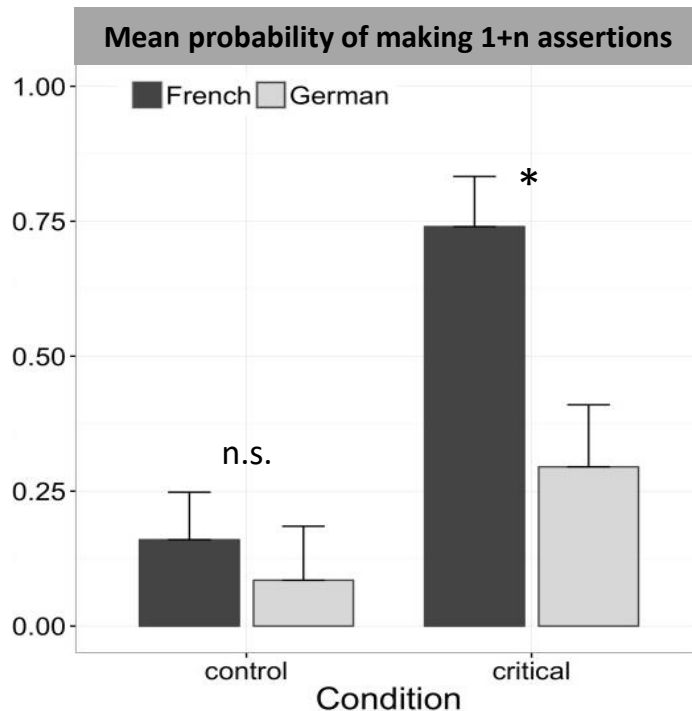

control

change in direction

# Results: event description

## Typical responses control condition:

German: *Ein Motorradfahrer **fährt** eine Gasse entlang.*

French: *Un scooter **passe** dans une rue pavée.*

## Typical responses critical condition:

German: *Ein Ball **rollt** die Treppe runter.*

French: *Une balle **roule** et **descend** des escaliers*

## Exp. 2: event segmentation

Languages: German, French (new groups)

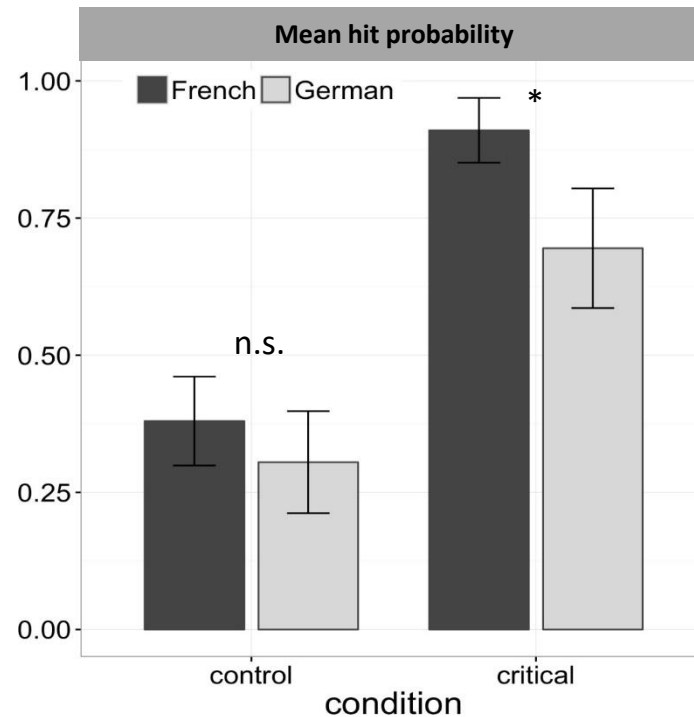

Critical stimuli: same as in study I

Control stimuli: same as in study I

Task: “press a button whenever you think one activity ends, and a new one begins”

# Results: event segmentation

- ‘hit probability’: the probability of pressing the button at least once per video
- Control: low likelihood of perceiving changes in activity
- **Critical**: higher likelihood of perceiving activity changes → more so in **French**, than German

# Summary

Differences in segmentation frequency French & German:

- **French:** A change in direction triggers the use of a new verb, e.g.,  
'roule et descend'

→ Segmentation on the basis of changes in direction of the Figure

- **German:** Changes in direction packaged into a single clause, e.g.,  
'rollt die treppe runter'

→ Events are segmented and perceived holistically

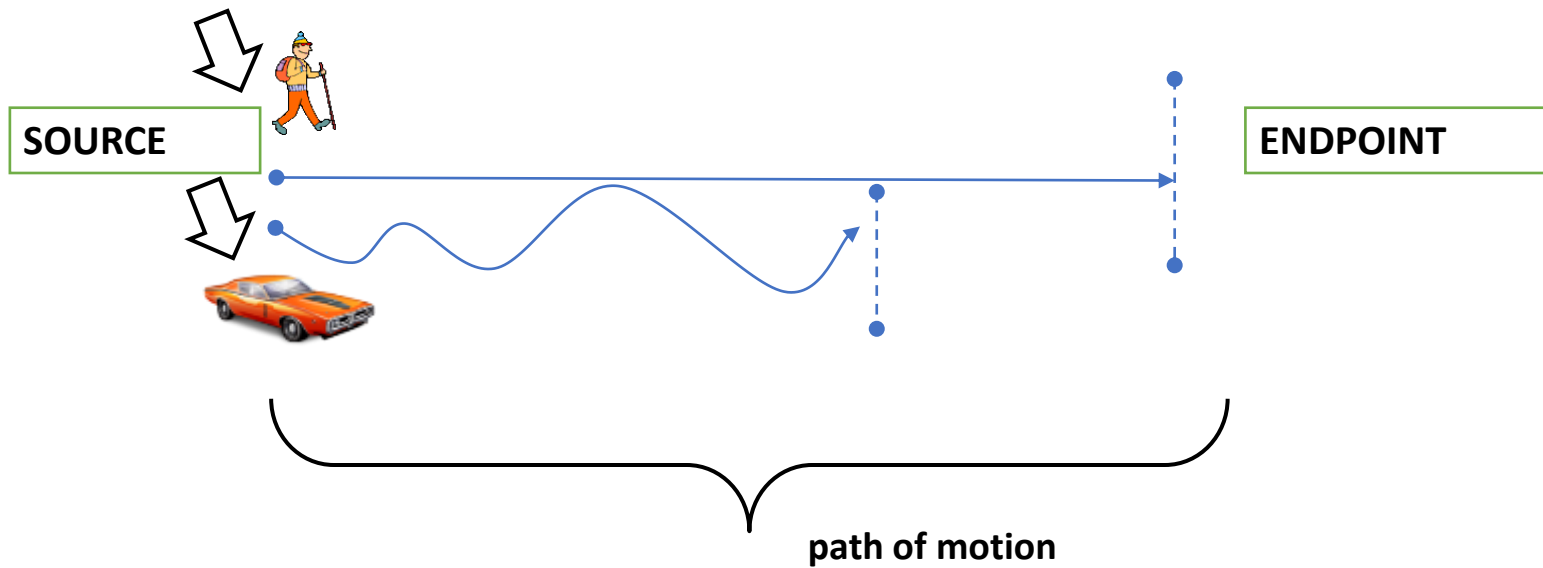

❖ The way in which events are chunked and packaged linguistically is also reflected in the way people perceive and segment events in general (without speaking)

❖ **Verbs** (semantics) define what we perceive to be an event

# Zooming in on satellite-/verb-framing

- Path verbs: From what element is path information derived?

Manner of motion

# Path conceptualization

Verb-framed

Path verbs: Figure-based

*Se diriger vers*  
*S'approcher*

Ground-contours implicit

Figure/moving entity

SOURCE

ENDPOINT

Ground

Satellite-framed

Manner verbs + Ground-based satellites:  
*To walk/drive along*

# Implications for processing and L2 learning

Motion directed towards endpoint (not reached)

“What is happening in the video?”

**Conceptualization:**  
**What to say?**  
- Perspective-taking  
- Information selection

**Focus** on Figure/moving entity may differ depending on the L1  
→ Eye tracking method

## Early stages of sentence planning:

- Information relevant to **verb** selection important
- Using **Figure-based Path** verbs requires an assessment of the spatial relation between Figure and Endpoint (*s'avancer vers* vs. *s'approcher* vs. *marcher*?)
- Using **Ground-based** concepts, less so (*walk toward*)

Highly automatized processes:

- An **L2** speaker may rely on processing routines as used in the L1
- Conceptual transfer, as reflected in **eye movement (attention)** patterns during sentence planning

# Tracing trajectories

Participants (N=20 per group):

- German native speakers (Heidelberg Uni)
- French native speakers (Paris 8)
- Advanced French L2 learners of German (Heidelberg Uni, immersed in German environment, minimum C1 proficiency level)

Stimuli:

- Motion events with varying degree of directionality towards an endpoint (all *not* reaching endpoints) (see paper for details 😊)

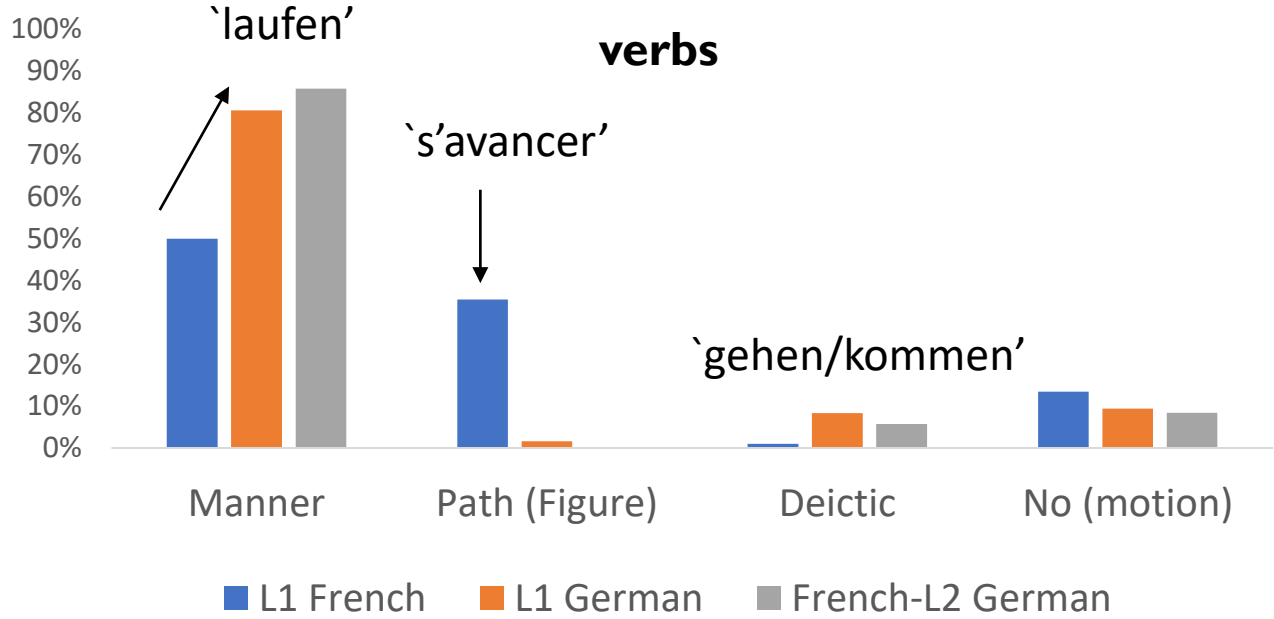

# Procedure

*“describe what is happening in the videos”*

- LI French -> in **French**
- **LI** German -> in **German**
- French-**L2**German -> in **German**
  
- Analysis of event descriptions:
  - Manner/Path information encoded in verbs plus verb satellites
  
- Analysis of eye movements during scene inspection + verbalization
  - Focus on fixations in two areas of interest:  
**Figure/Moving Entity** (+ **Endpoint**)

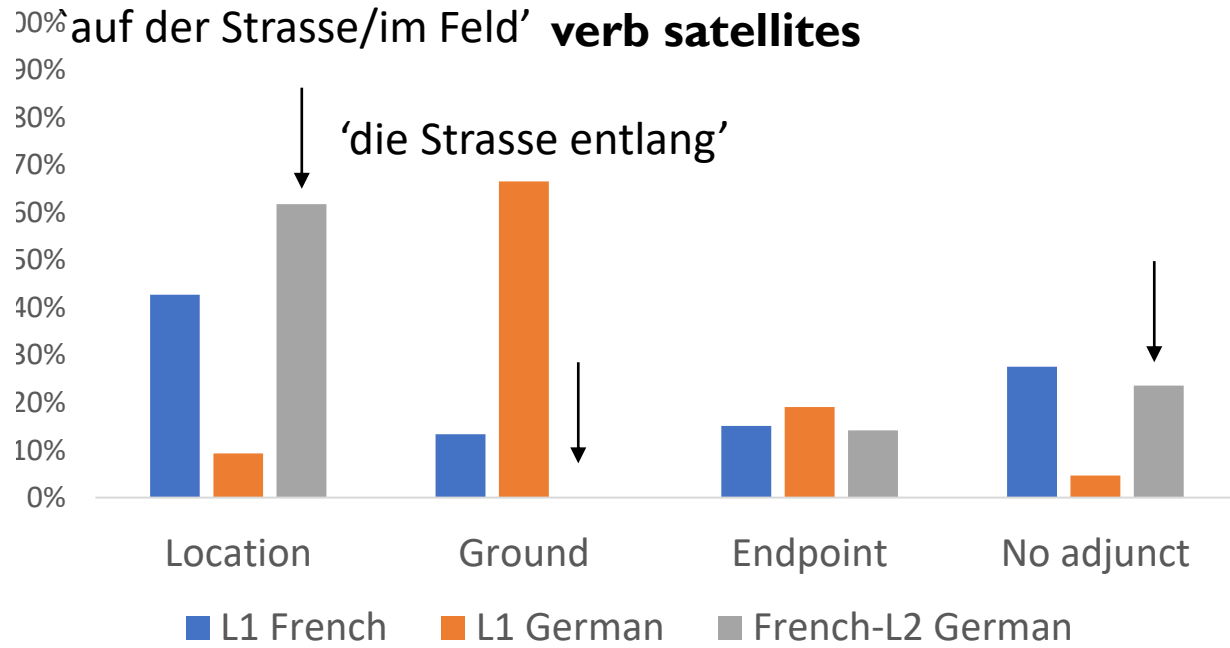

**Verbs:**  
 French-L2 German  
 – mainly manner verbs  
 (target-like)

**Satellites:**  
 French-L2 German  
 – mainly location adjuncts  
 (L1 French-like)

**L1 German:**  
*Eine Frau laeuft eine Strasse entlang*

**L2 German:**  
*Eine Frau laeuft auf der Strasse.*  
*Eine Frau laeuft.*

### L1 French:

*more early looks to Figure*

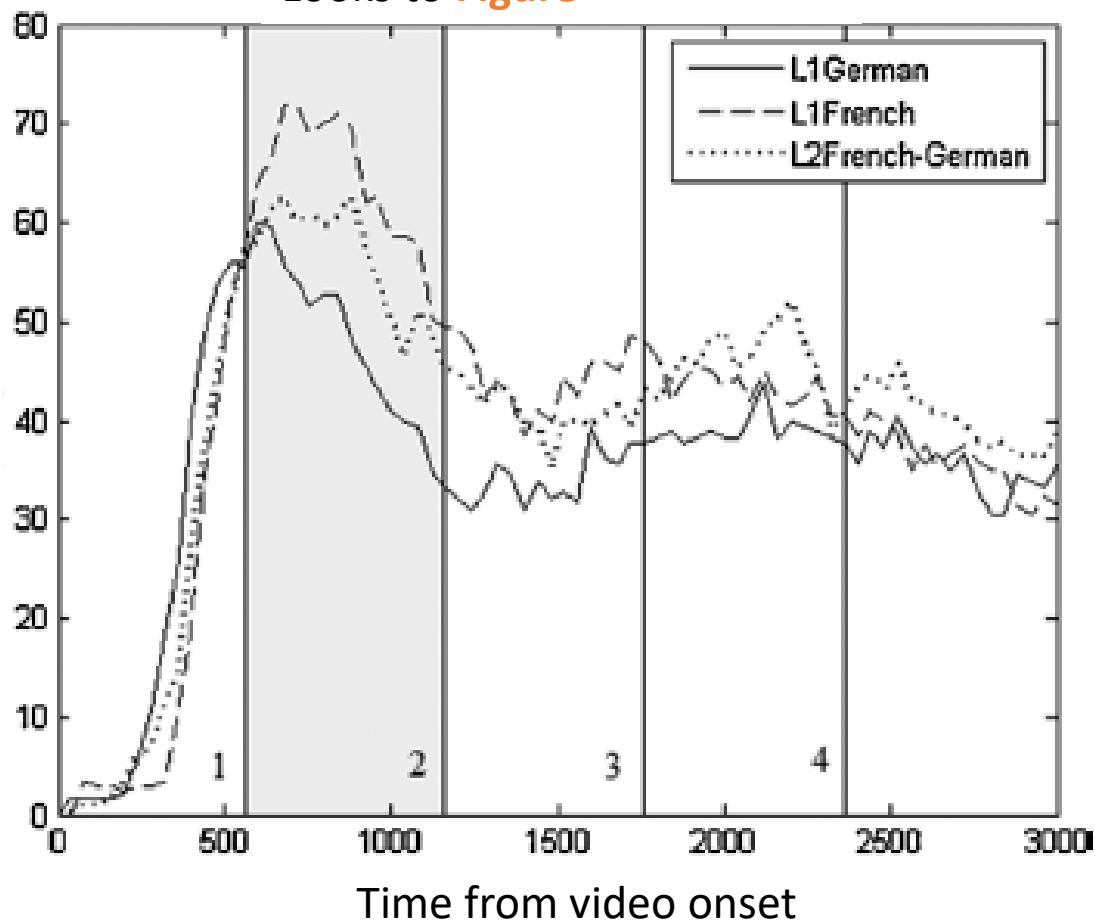

### French-L2German:

pattern in between L1French and L1German

→ L2German: despite target-like use of manner verbs, their looks are quite **Figure**-focused

→ L2German descriptions are figure-focused too:  
 - Manner verbs plus location adjuncts or single Manner verbs

Looks to **Figure**

# Discussion: L2 learning

- **Conceptual transfer**; only *partly* reflected in the language data
  - target-like use of Manner verbs, but use (or lack of) verb satellites evidences LI-centred event conceptualization (Figure based -> locating the Figure in space)  
(see also Berthele & Stocker, 2017; Stefanowitsch, 2013)
  - LI-centred event conceptualization pattern evident from the eye movement data, reflecting early scene processing and sentence planning processes
- **L2 event conceptualization** (even at highly advanced levels) shows an intricate interplay of LI-based processing routines and both LI/L2-based 'output'

# Discussion: xling differences

- In French, and also other languages with verb-framed features (e.g., Mandarin with variety of Path-verbs; Liao et al. 2019), events are conceptualized with a strong focus on the **Figure**
- This is reflected in
  - Description patterns: Use of **Figure-based path** verbs / Manner verbs + **Location**
  - Eye movement patterns while inspecting the scenes for verbalization: early looks towards Figure's orientation and distance to goal
  - Event segmentation patterns: French speakers segment videos of motion on the bases of changes in the direction of a Figure (Gerwien & v. Stutterheim, 2018)
- Crosslinguistic differences between **verb- and satellite-framed** languages in cognitive saliency of Figure, akin to previous differences in cognitive saliency of **Manner vs Path**

# Manner-saliency electrified: “Minding the manner”

- Speakers of satellite-framed languages show more attention to Manner of motion than speakers of verb-framed languages (e.g., Soroli et al., 2010; Gennari et al., 2002)
- ✓ What about **nonverbal** attention patterns?
  - Mixed evidence (e.g., Papafragou et al. 2008; Filipovic, 2010; Montero-Melis et al., 2016)
- ✓ What about **early bilingual** speakers? (i.e., speakers growing up with a satellite- + a verb-framed language from birth/before 4 years)
  - Suppress habitual expression of manner in their **Verb-framed language**
  - Combine manner information with **path (ground/goal)**-information in their **Satellite-framed language**

# Method

## Participants:

- Native speakers of Dutch
- Early bilingual speakers of **Turkish** (verb-framed) and **Dutch** (satellite-framed), residing in the Netherlands (heritage speakers)

## Video-picture matching task, with **EEG** recording (carried out in Dutch setting)

- Type of overlap (manner/path-endpoint) between video and picture is manipulated
- Oddball design (frequency manipulation)

# Picture matching task

‘Press a button when the **picture** looks exactly like the scene depicted in the video clip’

Tapping into **implicit** effects of a viewer’s language background on perception

- EEG: ms by ms brain responses
- How fast does the brain pick up a difference/overlap in terms of Manner/Path-Endpoint between video and picture? Language differences?

- \*ERP\***
- **P300**: between 350 and 700ms after picture onset -> **attention**
  - **Late Positivity**: between 700 and 1000ms after picture onset -> **reanalysis/’check’**

# Conditions

Oddball conditions should trigger stronger **P300/Late Positivity** brain responses -> processed with more attention and/or requiring an extra analysis or check

Differential processing of Endpoint(Path)/Manner match conditions?

**walk** to a **barrier**      **Full match** **skate** to a **tunnel**      **Endpoint match** **walk** to a **tunnel**      **Manner match** **skate** to a **barrier**      **skate** to a **tunnel**

Video

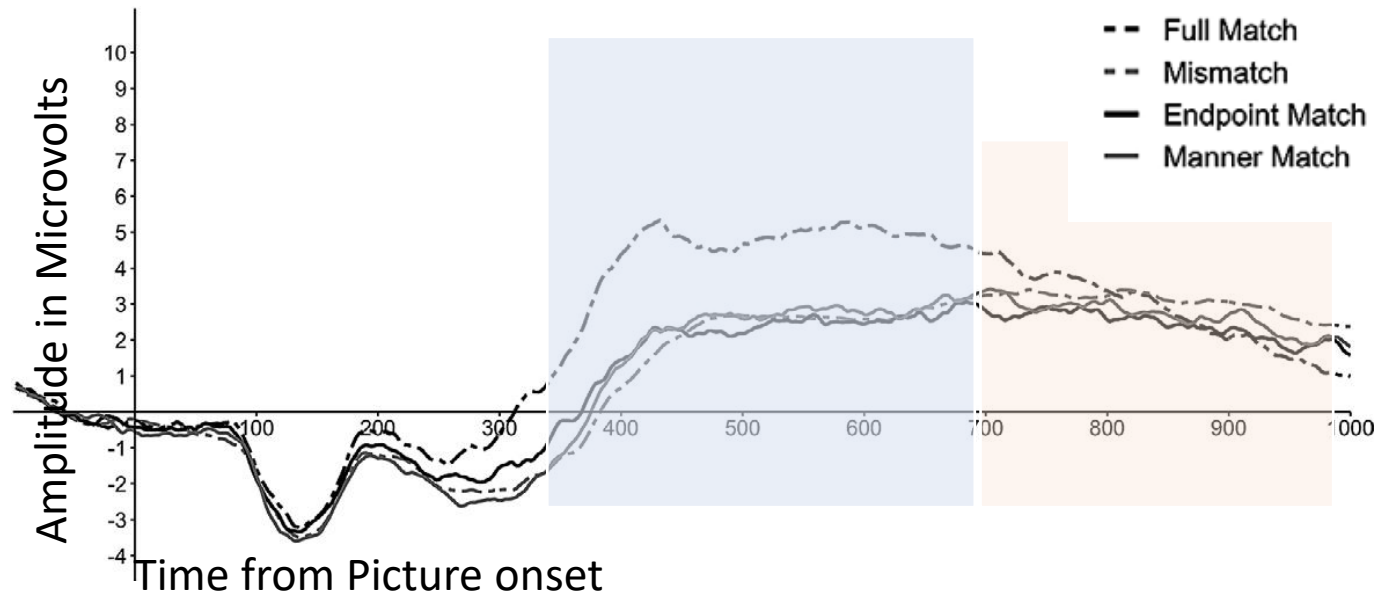

Picture

Infrequent (oddball) conditions: each occurring only in 10% of trials (40 times)

# Results

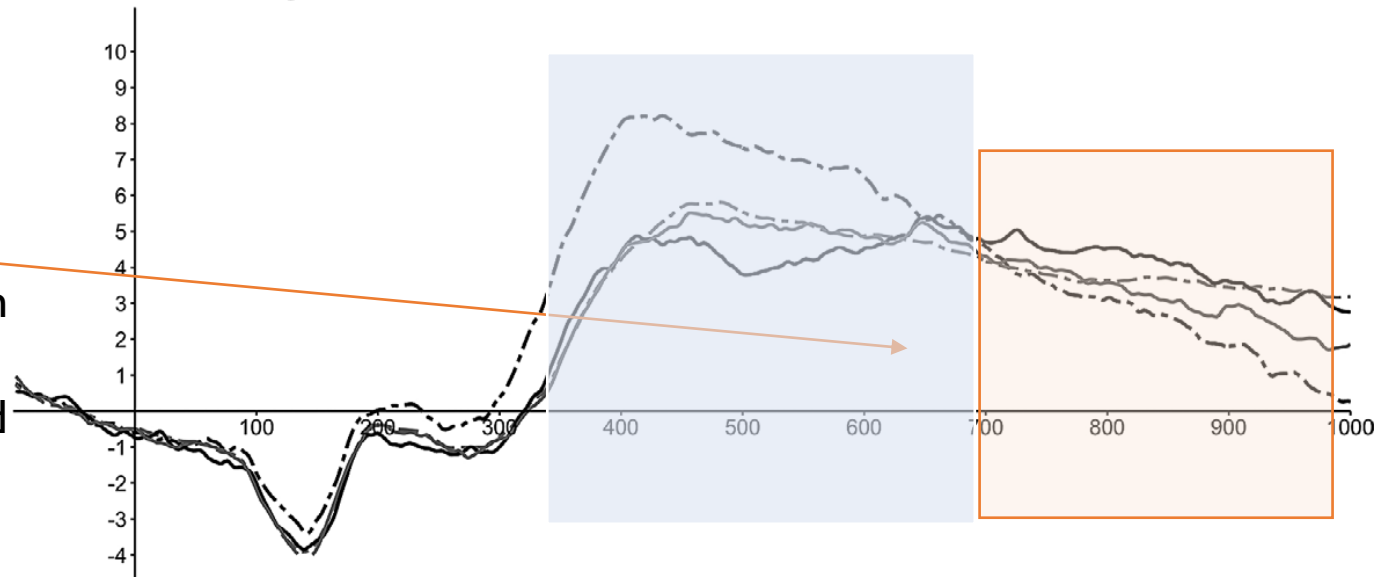

No group differences in task-related **attention** (P300: 350-700ms)  
→ Equal attention to Path and Manner

Dutch Controls: Frontal-Central Electrodes

In **Turkish-Dutch bilinguals**, more reanalysis/extra check (Late Pos.) for **Endpoint-match** than Manner-match condition

Turkish-Dutch Bilinguals: Frontal-Central Electrodes

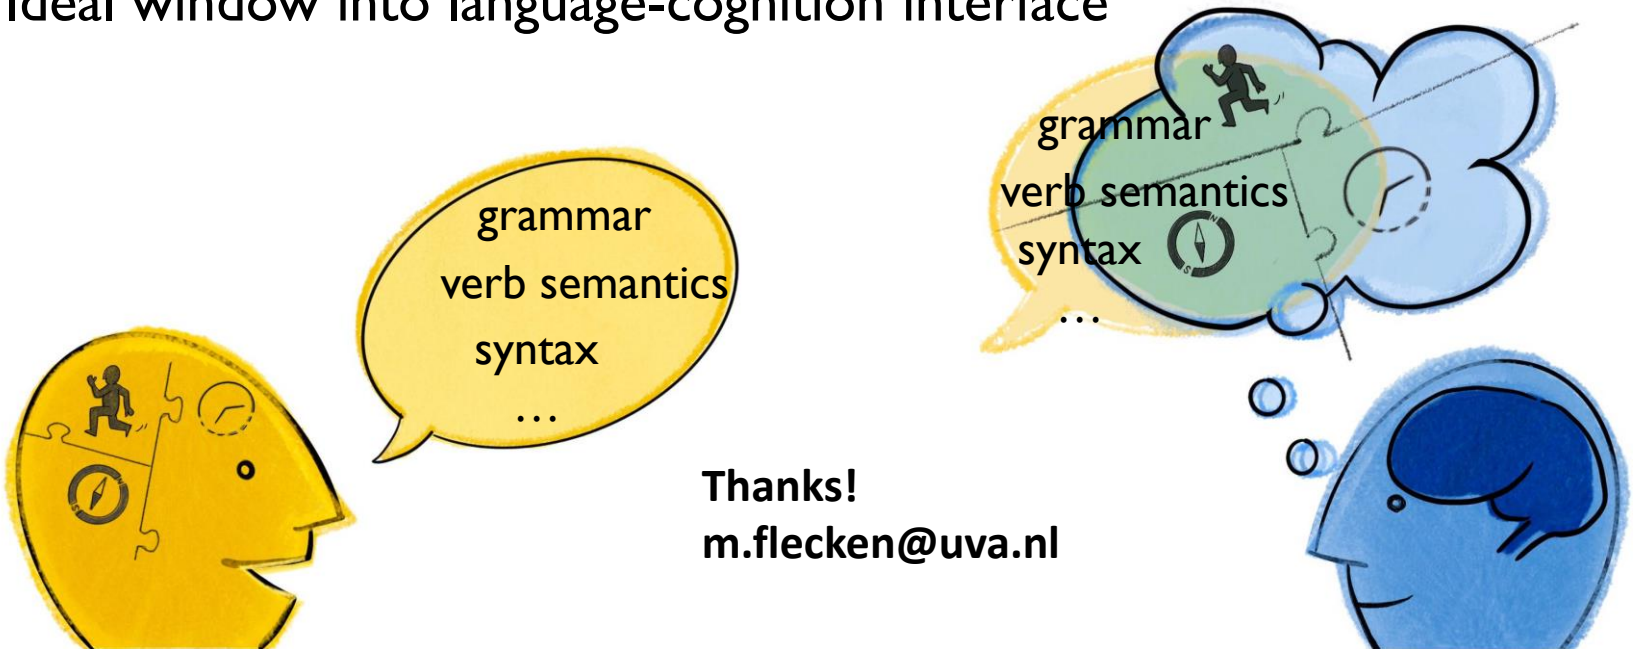

→ **reanalysis**/enhanced processing of **Path**-information  
→ Driven by **Turkish?**

# Summary: Motion events

- Differential processing of **Path** (Figure) (vs. Manner) of motion information in **L2 learners** and **early bilinguals** of typologically different languages
- Verb- / Satellite-framing has cognitive consequences
- Such consequences can be captured in both verbal and nonverbal tasks, using time-sensitive methods
  - These cognitive biases are found within 1 sec after people are presented with depictions of motion events!

- **Variation** in linguistic event description [verb- vs satellite-framing] is reflected in cognitive processes
  - Processing differs in native speakers vs L2 learners and bilinguals, as a result of conceptual transfer or convergence
  - **Events** as critical units of representation in both language and cognition
- Ideal window into language-cognition interface

Thanks!
